

1. Buffering	<p>Queue of messages attached to the link</p> <p>Three ways:</p> <ul style="list-style-type: none"> > zero capacity: no messages are queued on a link sender must wait for the receiver > bounded capacity: finite length of n messages > unbounded: infinite length 	5. Naming: Direct communication (properties)	<p>Must name each other explicitly:</p> <ul style="list-style-type: none"> > send(P, Message); send message to p <p>Properties</p> <ul style="list-style-type: none"> > links are established automatically > a link is associated to one pair of communicating processes > between each pair there exists exactly one link > the link may be unidirectional, but usually bi-directional
2. Communications in client-server systems	<p>Sockets</p> <ul style="list-style-type: none"> > endpoint for communication (161.25.19.8:1625) <p>Remote Procedure calls</p> <ul style="list-style-type: none"> > used between systems with network connections <p>pipes</p> <ul style="list-style-type: none"> > allows two processes to communicate <p>Unix signals</p> <ul style="list-style-type: none"> > used to notify the process of an event 	6. Producer Consumer buffers	<p>Unbounded: no practical limit on the size of the buffer</p> <p>Bounded: assumes that there is a fixed buffer size</p>
3. Indirect Communication (properties of communication link)	<p>Messages are directed to and received from mailboxes</p> <ul style="list-style-type: none"> > each mailbox has a unique id <p>Properties</p> <ul style="list-style-type: none"> > link is established only if processes share a common mailbox > A link may be associated with many processes each pair of processes may share several communication links > may be unidirectional or bi-directional 	7. Shared Memory	<ul style="list-style-type: none"> > Area of memory shared among the processes that wish to communicate > Communication is under the control of the users processes not the OS
4. Message passing (2 steps, implementation)	<p>Processes communicate with each other without resorting to shared variables.</p> <ul style="list-style-type: none"> > if Processes p and q wish to communicate they need to : >>> establish a Communication link between them >>> exchange messages via send/receive <p>Implementation</p> <ul style="list-style-type: none"> > physical: memory hardware bus, network > logical: direct or indirect, synchronous or asynchronous, automatic or explicit buffering 	8. Synchronizaton	<p>Message passing may be either blocking or non blocking</p> <ul style="list-style-type: none"> > blocking is synchronous >>> sending or receiving blocks > non-blocking is considered asynchronous
		9. Two models of IPC	<p>Shared Memory</p> <p>Message Passing</p>
		10. Types of Pipes	<p>Ordinary</p> <p>Allows communication in standard producer consumer style</p> <ul style="list-style-type: none"> > producer writes to one end, consumer reads from the other end > requires parent-child relationship <p>Named</p> <ul style="list-style-type: none"> > no parent-child relationship needed > several processes can use the same named pipe
